the current understanding of viruses are
shown in the timeline in Figure 1.1.

1. Introduction. Plant viruses are one of the most economical devastating microorganisms that lead to crop losses and serious threats to food security. In response to viral infection, plants have evolved the multilayered antiviral mechanisms including gene silencing and resistance (R) gene-mediated resistance. Role of autophagy during plant-virus interactions ... Most plant viruses are transmitted horizontally and re-transmitted by plant-feeding organisms (vectors) that are able to move from plant to plant [1,2]. The most frequent vectors of plant viruses are hemipteran and thysanopteran insects with piercing-sucking mouthparts, including aphids, whiteflies, leafhoppers, planthoppers,

 The viruses have the "machinery" to enter the animal cells directly by fusing with the cell membrane (e.g. in the nasal lining or gut). By contrast, plant cells have a robust cell wall and viruses cannot penetrate them unaided. Introduction to

plant viruses
 Plant viruses are often spread from plant to plant by organisms . These are normally insects, but some fungi , nematode worms and single-celled organisms have been shown to be vectors. When control of plant virus infections is considered economical (perennial fruits, for example) efforts are concentrated on killing the vectors and removing alternate hosts such as weeds.
